12	16.1. Introduction: The Specificity of Peri-urban Agricultural Areas: A	12
13	Context of Extreme Competition for Access to Resources	13
14		14
15	Empirical observation of the forms of agriculture developing on the periphery	15
16	of cities reveals the generalized presence of particular types of production or	16
17	commercialization, which explains why certain sectors, such as the vegetable	17
18	growing industry or the associated agricultural production, are sometimes called	18
19	“peri-urban agro-industries”.	19
20	However, two factors make it difficult to identify the production sectors that	20
21	are specifically peri-urban: the first is the existence of a large variety of localized	21
22	agricultural systems in peri-urban areas (see the high concentration of cereal	22
23	growing on the periphery of Paris); and the second is the presence, in rural areas,	23
24	of the same forms of food agriculture. Given this finding, most of the scientific	24
25	community agrees that the specificity of the peri-urban sectors of agricultural	25
26	production remains to be demonstrated, but that the specific nature of peri-urban	26
27	land itself is undeniable. Its specificity lies in the fact that an increasing number	27
28	of users compete for access to resources and land that have been traditionally	28
29	reserved for agriculture.	29
30	The idea that peri-urban agriculture is above all defined by the state and location	30
31	of the exploited resources is expressed by the concept of ‘urban agriculture’,	31
32	proposed by Mougeot (2000):	32
33		33
34	Urban agriculture is an industry located within (intra-urban agriculture) or in the	34
35	fringe (peri-urban agriculture) of a town, a city or a metropolis, which grows	35
36	and raises, processes and distributes a diversity of food and non-food products,	36
37	(re-) using largely human and material resources, products and services found in	37
38	and around that urban area, and in turn supplying human and material resources,	38
39	products and services mainly to that urban area.	39
40		40
41	Moustier and Salam Fall (2004) use and add to this definition by specifying	41
42	that all agricultural systems located in an urban area (therefore peri-urban	42
43	area) are at the heart of resources that are used for both agricultural production	43
44	activities and industrial and other urban activities. This common need for and use	44

1 of these resources can generate valuable productive synergies, but might also be 1
 2 at the origin of competition between the various systems of production for the 2
 3 consumption of territorial resources. 3

4 The territorial dimension of the peri-urban agricultural systems therefore lies 4
 5 in the existence of localized resources that are shared between an agricultural 5
 6 system and the closest urban centre, within what can be called an *agri-urban* 6
 7 *ecosystem*. At the scale of a territory, the urban productive systems consume, at 7
 8 the starting point, flows of primary raw materials (water, air, soil) or transformed 8
 9 materials (products from the primary sector, among which agriculture) produced 9
 10 from a stock of natural resources. As an output, they accumulate waste materials 10
 11 that must be exported to other territories, stored on site, or recycled so as to replace 11
 12 the stock of raw materials. Agricultural production systems are doubly connected 12
 13 to this network of material flows. On the one hand, they supply food and raw 13
 14 materials to the city. And on the other, they absorb part of the waste generated 14
 15 by the city (horse manure, wastewater, and nowadays bio-solids and composting 15
 16 products) by reincorporating it into the cycle of the agri-urban ecosystem (see 16
 17 Figure 16.1). 17

18 By extension, we call 'agri-urban resources' the resources that circulate 18
 19 between the agricultural and the urban systems and which are usable for both 19
 20 agricultural production and for urban consumption. These resources include 20
 21 unbuilt-up land, water, air, and certain 'produced' resources such as landscape 21
 22 resources, food products or urban waste, all resources that can be incorporated into 22
 23 the agricultural production cycle. 23

44 **Figure 16.1** Graphic representation of the agri-urban ecosystem 44

1 16.1.1. *A competitive system that generates conflicts* 1

2 2

3 In areas where available resources are limited, the strong competition between the 3
4 uses that consume these resources causes increasing conflicts and tensions. This 4
5 is true in the case of agri-urban resources, which in peri-urban areas, are covered 5
6 by a diversity of users who perform different, often antagonistic activities (Bryant, 6
7 1992). The spatial expansion of cities is, indeed, a process that consumes natural, 7
8 agricultural or forestland and that generates nuisances and pollutants transmitted 8
9 through certain 'mobile' resources such as water or air. This universal finding 9
10 conceals the fact that there is a diversity of ways in which built land expansion 10
11 takes place, ways that do not always have the same impacts on the functioning of 11
12 agricultural territories. 12

13 For a long time, this expansion took place through the progressive occupation 13
14 of the closest land to the urban area. Bryant shows, at the end of the 1970s, 14
15 that the ways in which land was appropriated when the large-scale projects of 15
16 development of the suburban areas around Paris were realized have in some 16
17 cases helped to improve the conditions of exploitation of agricultural land, thanks 17
18 to the re-investment of the sale proceeds into the productive sectors (Bryant, 18
19 1973a). Furthermore, the growth of the urban market can provide an interesting 19
20 opportunity for business expansion; indeed, during that period a number of fruit 20
21 farmers expanded their acreage so as to be able to meet the demand of the urban 21
22 population (Bryant, 1973b). 22

23 In the more recent model of urban sprawl, that of the dispersed city and 23
24 of increasingly uncontrolled and fragmented urban expansion, agricultural 24
25 land use has become durably 'interstitial', despite the fact that most of the 25
26 land is still used for agriculture. Indeed, only 10 to 15 per cent of the land 26
27 area in today's peri-urban belts is 'artificialized' (i.e. built or developed by 27
28 man) (Boisson 2005); which means that over 80 per cent of the remaining 28
29 space consists of open land, most of which is used for agriculture. 29
30 At the scale of France, 40 per cent of all agricultural land is located within urban 30
31 areas (see Figure 16.2). 31

32 Even though their consumption of agricultural land has been controlled 32
33 or at least slowed down (IAURIF, 2005), these rural areas under metropolitan 33
34 influence serve as support for the increasingly complex intermingling of the 34
35 functional farmland and city. Moreover, the discontinuation of public investment 35
36 in the large-scale programmes of urban development has reduced the margins 36
37 of negotiations based on the expropriation indemnities received by the farmers. 37
38 Neighbourhood tensions and conflicts are therefore fostered by this new peri- 38
39 urban environment, and land exchanges do not lead to the investments that are 39
40 necessary to reorganize the systems of exploitation. Conflicts are often considered 40
41 as signs of the dysfunction of the social structures within peri-urban territories that 41
42 must be resolved (Owen et al., 2000). Our research hypothesis, however, takes 42
43 an opposite approach and supports the idea that conflicts contribute to the social 43
44 control of the use of agri-urban resources. 44

Figure 16.2 Location of agricultural land within urban areas

Notes

Striped area = Urban areas (urban poles, peri-urban, mono or multi-polarized municipalities)

Remaining = Agricultural space (Data Corine Land Cover 2000)

- The analyses presented in this article are geared to three research objectives:
- Identify the objects and resources, the uses of which are regulated through conflictual processes;
- Evaluate the scales of action implemented by the local actors according to the space-related issues from which conflict arises;
- Highlight the socio-economic situations that combine the spatial and social conditions that are conducive to the actors' engaging in conflict.

For this purpose, we have performed a quantitative inventory of the conflicts related to the use of agri-urban resources, located within the Greater Paris Region. Section 16.1 of this chapter presents the geographical context, the conceptual

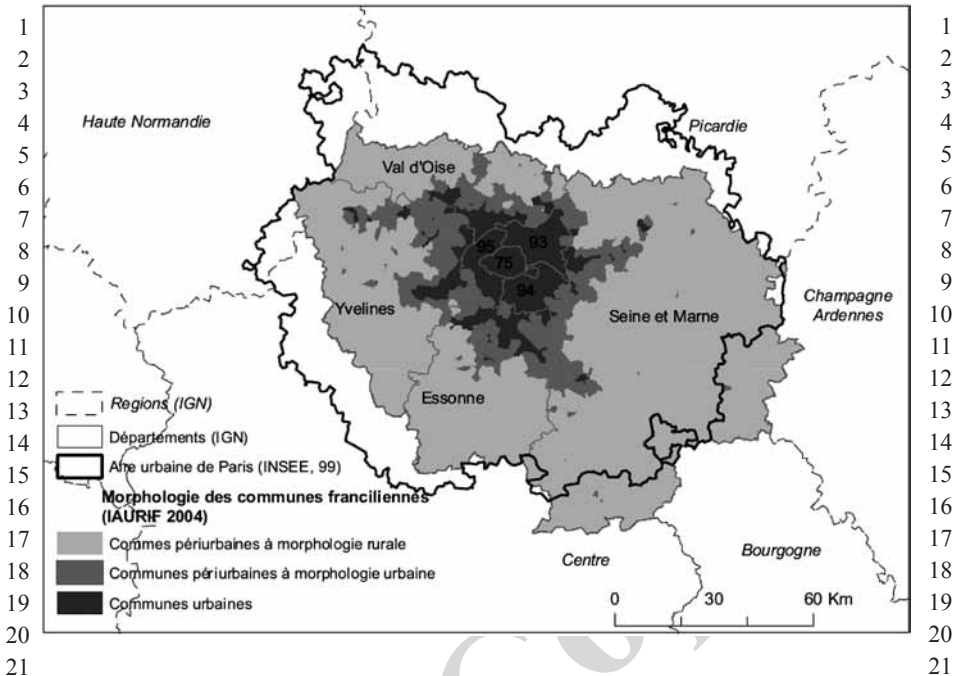

Figure 16.3 The various spatial and political-administrative discontinuities in the Greater Paris Region

framework, and the inventory method we have used. The results of the inventory and the analysis of the data are detailed in Section 16.2, in which they are presented according to the three research objectives we have set for ourselves.

16.2. Conflicts Related to the Use of Agri-urban Resources: Context, Concepts and Research Methods

16.2.1. The Greater Paris Region, a region representative of the diversity of peri-urban dynamics

The Greater Paris Region is by far the largest metropolitan area in France and can only be compared to two or three other metropolises of similar sizes in Europe. The national capital region is: the country's financial and industrial centre; the region with the highest number of tourists; and, in terms of its layout, the archetype of a radial-concentric city in spite of the urban outgrowths extending in the form of fingers along the valleys of the rivers Seine, Marne and Oise (see Figure 16.3). While 50 per cent of its total land area is used for agriculture, it is one of the first regional bodies to have actively acknowledged the importance of developing the land in a sustainable manner so as to protect agricultural land and ensure the

1 survival of farming enterprises. The most recent sign of this commitment of the 1
 2 regional authorities has been their recognition of, and support to, local initiatives 2
 3 for the conservation of agricultural land in inter-municipal areas under strong 3
 4 urban pressure ('agri-urban programmes'), as well as of the four Regional Nature 4
 5 Parks situated within the rural belt. 5

6 The tensions caused by the existence in the same area of antagonistic activities 6
 7 inherent to the multifunctionality of the peri-urban space are many and acute not 7
 8 only because of the scarcity of space but also because of the high diversity of 8
 9 production activities and of the local populations. 9

10 10

11 16.2.2. *Conceptual framework of the analysis of land-use conflicts* 11

12 12

13 *Conceptual definition of a land-use conflict* 13

14 Several publications have examined conflicts and analysed their development and 14
 15 local characteristics (Melé and Rosenberg, 2003; Kirat and Torre, 2005). Most 15
 16 authors have found that the diversity of tensions related to the many uses of land 16
 17 makes them, on the whole, difficult to observe and survey: as they are not always 17
 18 expressed, trying to make an inventory of them would be unrealistic. Focusing 18
 19 exclusively on actual protests (Rucht et al., 1992) would drastically narrow the 19
 20 field of observation, at the risk of missing out on interesting information¹ (Trudelle, 20
 21 2003). An intermediate option – certainly the most open and operational – is 21
 22 to identify conflict through the observation of the act of opposition of at least 22
 23 one of the protagonists; it is this act, limited in time and space, that indicates a 23
 24 crystallization of the tensions. 24

25 Analyses based on game theory use the notion of 'credible engagement' or 25
 26 'commitment' to conceptualize this action (Caron and Torre, 2005). Engagement 26
 27 manifests itself in more or less institutional forms (verbal opposition, placards, 27
 28 registered letters, administrative proceedings...), or in more or less radical ways 28
 29 (assault, signs forbidding access, fences...). Defined in this manner, conflict can 29
 30 be identified more easily using direct or indirect information, and this definition is 30
 31 then adapted to a quantitative approach to conflictuality. We define as conflict an 31
 32 *opposition between actors with antagonistic goals, an opposition that leads to the* 32
 33 *credible engagement of at least one of the parties.* 33

34 34

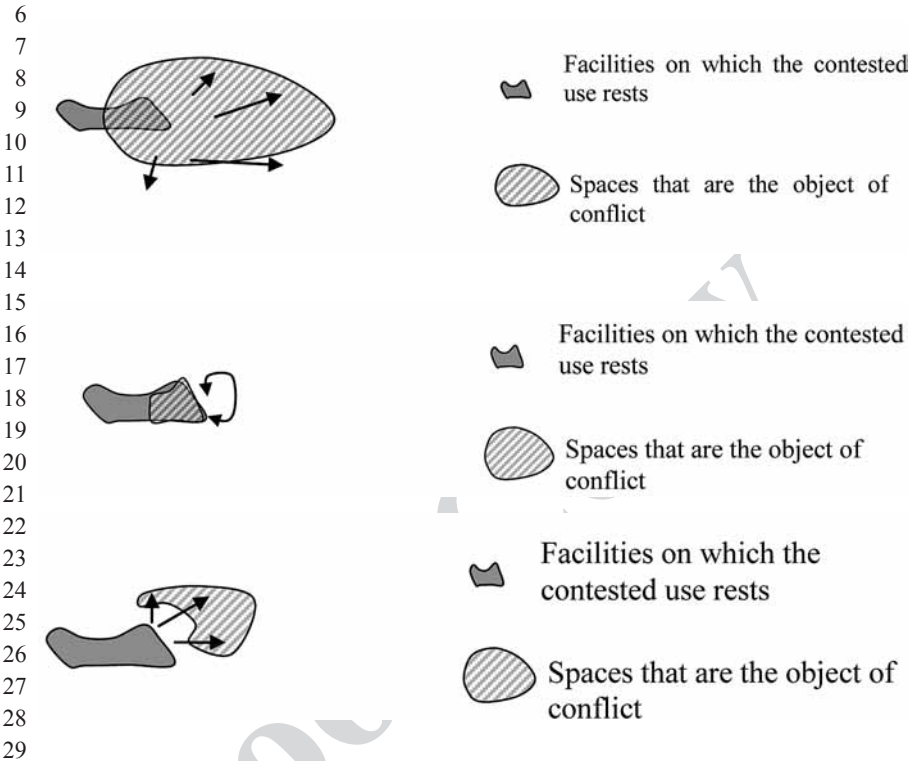

35 *The spatial dimension of land-use conflicts: between contested activities and* 35 36 *protected resources* 36

37 More than the use itself, it is its location within an area occupied by other users 37
 38 that is contested during conflicts. In these situations, it is more precisely the object 38
 39 or facilities on which the contested activity rests that generates the conflictual 39
 40 reaction of the actors. This reaction is related to the antagonisms which arise 40
 41 from several uses conflicting with one another. These antagonisms can be found 41

42 42

43 ¹ While the term 'conflictual activity' covers all acts or deeds of opposition, the 43
 44 expression 'protest activity' implies collective action and a physical manifestation. 44

1 within a perimeter that corresponds to the physical characteristics of the contested 1
 2 facilities, but they can also concern a neighbouring area affected by a nuisance 2
 3 caused by the use of these facilities. Therefore, all the areas whose characteristics 3
 4 are altered by the contested use of these facilities will be considered as the spaces 4
 5 that are the object of conflict. 5

30 **Figure 16.4 The different spaces that are the object of conflict** 30

31 32 The physical characteristics of the spaces that are the object of conflict vary: 32

33 (1) The resources whose state or conditions of use are constrained by the object 33
 34 of conflict are located within the perimeter of this object. This is the case for some 34
 35 conflicts related to the zoning designated in urban plans, in which some parcels of 35
 36 land are classified as land that cannot be built on (for example, conflict between 36
 37 people who wish to protect the land from being built on, and those who want to use 37
 38 it for residential purposes). It is also the case when urbanization projects alter the 38
 39 characteristics of rural landscapes. Thus, residences built illegally in agricultural 39
 40 zones are contested not only 40
 41 because they are incompatible with conservation goals, as defined in the zoning 41
 42 plans, but also because they modify the rural landscape that the residents value as 42
 43 part of their living environment. 43

44

1 (2) The resources constrained by the contested facilities are located in areas 1
2 that are adjacent or close to the facilities in question. Thus, wild boar breeding 2
3 within private estates is not contested, but the damage caused by wild boars to 3
4 neighbouring farmers' crops lead to protests against the ways in which the estates 4
5 are managed. 5

6 (3) Finally, the parties who engage in conflict use the two arguments: the 6
7 contested new facilities represent a threat both to the resources on which several 7
8 users rest, and those located within neighbouring areas. Thus, projects of industrial 8
9 development are conducive to conflict not only because they are synonymous with 9
10 the production and emission of noise related or olfactory nuisance that will affect 10
11 neighbouring residential areas but also because it is suspected that the planned 11
12 factories will contaminate the soil on which they are built and destroy the natural 12
13 landscape resources present on the sites. 13

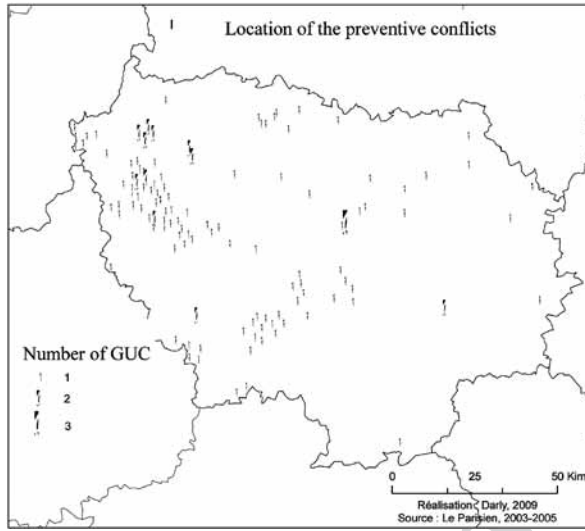

14 14
15 *Preventive and remedial conflicts* 15

16 Furthermore, a distinction is made (by borrowing two terms used in the medical 16
17 world) between *preventive* and *remedial* conflicts. In preventive conflicts, one 17
18 party anticipates the impact of a certain activity or use on space and protests 18
19 against it before the other party can implement it. The objective of the contesting 19
20 party is then to protect resources from possible degradation. 20

21 In these situations, the ability to determine the spaces that might be used for 21
22 undesirable activities depends on the accessibility of the information that makes 22
23 it possible to locate the contested facilities, and on the actors' ability to evaluate 23
24 the potential spatial extent of the nuisance and related risks. This evaluation – 24
25 which cannot be based on in-situ measurements – is strongly dependent on the 25
26 actors' experience of similar conflictual processes; the latter can indeed serve 26
27 as an experimental reference (see the case of the wind turbines with pro or con 27
28 arguments). In this regard, networks of people play a determinant role in the 28
29 exchange of experience and information. Depending on the nature of the contested 29
30 facilities, on the accessibility of the information concerning its characteristics, and, 30
31 finally, on the ability of the contesting party to model its impacts on the resources 31
32 present in the area, the zone under dispute may extend far beyond that of the 32
33 facilities in question. 33

34 *Remedial conflicts* are triggered when an effective degradation of the resources 34
35 has already been observed. The objective of the protesting parties is then to obtain 35
36 either the restoration of the resources in question to their initial state or benefits 36
37 or compensation for the harm incurred. The determination of the perimeter of 37
38 the affected area then strongly depends on the ways in which the nuisance or 38
39 risks are evaluated by the actors and is performed following two possible types 39
40 of chronological sequences. In the first type of sequence, one person or a group 40
41 of people experience a nuisance (by means of odour, noise, or otherwise) within 41
42 a certain area, which prompts them to look for and identify the source of this 42
43 nuisance, and possibly to adjust the initial perimeter of use and neighbourhood 43
44 incompatibility (the case of the pollution of water resources). Inversely, in the 44

1 second case, it is the identification of the object perceived as a potential source of 1
 2 nuisance that prompts certain parties to search for and identify the neighbouring 2
 3 areas at risk of being affected by the nuisance (see the example of agricultural 3
 4 silos: following a number of silo explosions, silos are now all subjected to risk 4
 5 assessments). 5

6 7 16.2.3. Inventory of the conflicts reported in the press: sources and methods 7

8 9 A first inventory of all the land-use conflicts reported in *Le Parisien* (regional 9
 10 daily newspaper) in 2005 (182 in total), indicated to us that agriculture is seldom 10
 11 the object of conflict and that the actors of the agricultural industry are rarely 11
 12 involved in conflicts. But 30 per cent of the conflicts are related to the non- 12
 13 agricultural use of open pieces of land identified as agricultural (cultivated, fallow, 13
 14 or meant for farming). Furthermore, this first inventory highlighted, firstly, that 14
 15 local elected representatives and associations are involved in the majority of the 15
 16 conflicts (70 per cent), and, secondly, that a large percentage of the conflicts are 16
 17 related not only to uses but also, more specifically, to land-use regulation (40 per 17
 18 cent of the conflicts). 18

19 We then extended the inventory of agriculture-related conflicts to cover two 19
 20 additional years (2003 and 2004), which enabled us to build a database containing 20
 21 90 conflicts of various scopes and intensities, related to the use of agri-urban 21
 22 resources. Compiled in the form of a relational database, the information found in 22
 23 the newspaper articles, once encoded, enabled us to locate the *communes* (i.e. 23
 24 French municipalities) in which one or several conflicts had occurred between 24
 25 2003 and 2005. Figures 16.5 and 16.6 represent the spatial distribution of these 25
 26 municipalities. 26

27 28 29 **16.3. Results: Geographical Characteristics of Land-use Conflicts: From** 29

30 **Objects to Social Processes** 30

31 32 Using the information gathered from the daily newspaper *Le Parisien* for the 32
 33 years 2003-2005, we first describe the diversity of the contested objects and 33
 34 the nature of the antagonisms they generate and which cause the actors' reaction. 34
 35 We then present the patterns of interaction between the various actors who oppose 35
 36 these different categories of objects. Finally, we evaluate the influence of the 36
 37 socio-economic situation in the municipalities on the probability of emergence of 37
 38 a conflict. 38

39 40 41 42 43 44

1 *16.3.1. Origins and spatial extension of conflicts related to the sharing of agri-* 1
2 *urban resources* 2

3 3
4 The information we collected enabled us to highlight the diversity of the facilities 4
5 contested by the actors at the origin of conflicts, as well as the different types of 5
6 antagonisms that explain their reaction. 6

7 7
8 *Nature and diversity of the contested facilities* 8

9 Conflicts related to the use of agri-urban resources are, for the most part, caused 9
10 by the extension and renewal of urbanized areas. These represent 63 per cent of all 10
11 land-use conflicts and are reported in 70 per cent of the newspaper articles. 11

12 This type of struggle involves a contest against certain urban activities, which 12
13 modify the state of agri-urban resources. The category that comprises the facilities 13
14 used for the management and processing of waste is the most significant in this 14
15 regard (it represents almost one-third of the conflicts related to the consequences 15
16 of urban expansion). However, these facilities are used for activities of different 16
17 natures, ranging from the burial of solid waste in landfills, the incorporation of 17
18 sewage treatment sludge waste into cultivated soil to the destruction of this waste 18
19 through incineration. The other categories of urban facilities at the origin of the 19
20 reported conflicts are, in order of importance, those related to housing, transport 20
21 and communication activities, and those related to trade, recreational and public 21
22 service activities (prisons, caravan parks). The other facilities that are directly 22
23 involved in urban extension at the expense of natural resources are related to 23
24 certain primary sector activities, such as wind energy extraction and production 24
25 (5.5 per cent of the conflicts are related to these two categories). Finally, 8 per 25
26 cent of the conflicts are caused by urban development regulations authorizing the 26
27 conversion of open spaces into urbanized or industrial zones. 27

28 The other non-agricultural uses (non-commercial and non-planned) of space 28
29 represent the second source of conflicts after those related to urbanization. 29
30 They were, between 2003 and 2005, at the origin of 18 per cent of the conflicts 30
31 inventoried and 17 per cent of those reported in the Press. They are related to the 31
32 residential use of agricultural land (uncleared, fallow or meadow land) by groups 32
33 of caravans or vehicles, and also to recreational uses such as hunting or motor 33
34 sports, which cause damage to crops. Some illegal uses of agricultural land, the 34
35 objects/equipment for which are not always identified, are part of this category of 35
36 uses (e.g. theft). 36

37 Finally, the conflicts related to agricultural uses of space or to the extension 37
38 of land for farming purposes represent the smallest percentage of the conflicts 38
39 reported in the press (the constraints they generate are at the origin of only 16 per 39
40 cent of the inventoried conflicts and 12 per cent of the press articles). In these 40
41 conflicts several categories of objects are contested. The first is that of agricultural 41
42 practices/facilities that are considered hazardous or dangerous (the illegal burning 42
43 of crop residues, the experimental use of GMO seeds, well-drilling for irrigated 43
44 crops). The second concerns the activities of storage and transformation of 44

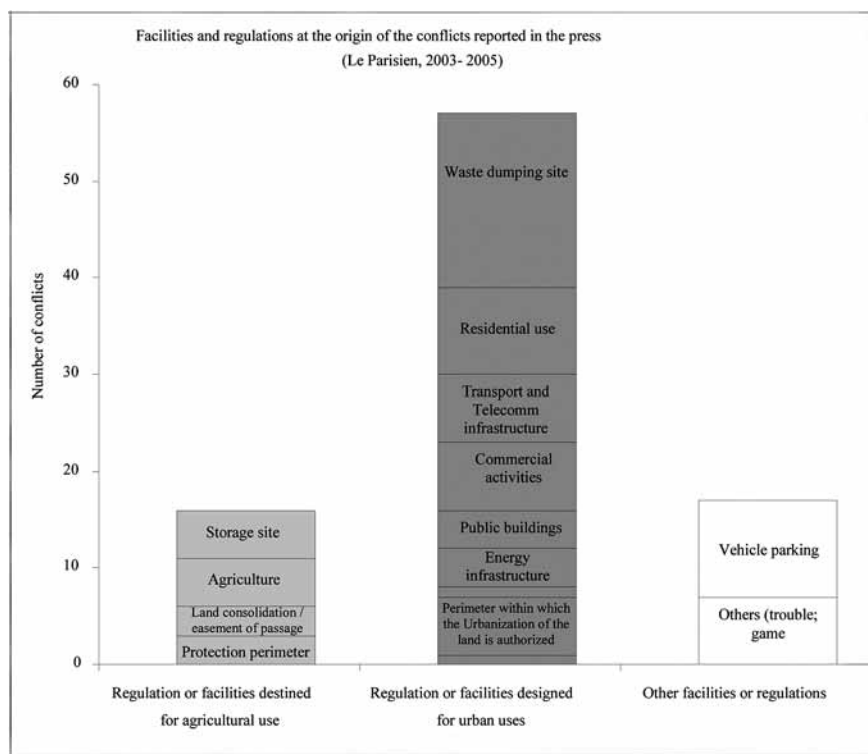

Figure 16.7 Proportion of the different categories of facilities or regulations at the origin of the 90 conflicts – reported in the Press – related to the use of agri-urban resources

Source: Le Parisien (2003 - 2005)

agricultural inputs and products, which necessitate the extension, development or functioning of industrial sites regulated as scheduled facilities (crop silos, the noise produced by beet trucks). The other conflicts in which actors protest against facilities developed for the agricultural use of land are directed against the adoption of regulations that restrict the use – urban or agricultural – of natural resources. The objects targeted by these processes of protest are therefore essentially the administrative boundaries that define the territory within which the protection measures (contested by the farmers themselves, who consider that the restrictions are too stringent) must be applied, but also the new parcel plans resulting from land consolidation operations (opposed by environmentalists because of the environmental consequences of the destruction of hedges) or even more local regulations that designate certain rural roads for agricultural use.

Figure 16.8 Proportion of remedial or preventive conflicts according to the type of facilities/objects contested

Source: Le Parisien, 2003-2005

Preventive conflicts

The majority of conflicts (57.7 per cent) occur in an attempt to prevent the creation or development of objects or facilities considered to be associated with environmental constraints (the other conflicts are remedial. They are triggered by people who seek to minimize or eliminate a nuisance they are already experiencing).

The conflicts related to facilities or regulations that are considered necessary for urban functioning are mostly preventive, with the exception of some categories such as waste management or residential use (Figure 16.8). Inversely, in almost all the conflicts related to other non-agricultural uses of space, the parties react and protest against objects that do exist and that have already modified the state of the resources. In these situations, the protesters start a process of remedial conflict. The cases of protests against facilities or regulations meant to enable certain parties to make agricultural use of natural resources are not as clear-cut.

1 Half of these cases concern virtual objects and uses (projects of agricultural well- 1
2 drilling, for example, or of genetically modified crops) whereas the other half 2
3 are protests against practices, buildings or regulations that already exist (stubble 3
4 burning, silos, easement of passage). 4
5 5
6 *The resources and interests threatened by the close proximity or juxtaposition of 6*
7 *incompatible land-uses* 7
8 People who protest against the existence or development of the types of facilities 8
9 we have just mentioned seek, above all, to protect individual or collective interests 9
10 related to the consumption, exploitation or conservation of territorial resources. 10
11 In almost half of the conflicts (46 per cent; Table 16.1), the actors fight for the 11
12 preservation of the agricultural use of certain local resources. The latter are 12
13 located within open spaces, or in some rare cases, within parcels of land that are 13
14 meant for agriculture but are 'used' for other activities (4 per cent of the cases). 14
15 These resources can be immovable natural resources, such as land, or 'mobile' 15
16 resources that circulate between close urbanized reas and agricultural land (water, 16
17 air). A large number of these conflicts (1/3 of them) are also cases where actors 17
18 join forces to fight for the preservation of the landscape resources and that of the 18
19 agricultural use of natural resources. 19
20 In 25 per cent of the conflicts, it is not so much the open spaces or landscapes that 20
21 the actors seek to preserve, but rather the environmental quality of the atmospheric 21
22 and water resources that circulate between the different peri-urban territories and 22
23 are used in residential zones. In these cases, the residents wish these resources to 23
24 circulate between agricultural, natural and residential spaces rather than between 24
25 future urbanized or industrial zones and their areas of residence. Finally, in 10 25
26 per cent of the conflicts reported in the press, the people who engage in a conflict 26
27 claim that they wish to protect agricultural land so as to ensure the preservation of 27
28 the biodiversity resources that it provides. 28

1	16.3.2. Land-use conflicts and interaction between the actors: Differentiating the	1
2	various patterns of opposition	2
3		3
4	Even though they are dependent on the nature and arrangement of objects/facilities	4
5	in space, conflicts are above all social processes that can be described in terms of	5
6	social interactions between groups of actors.	6
7		7
8	The interactions between the actors reveal that preventive conflicts are mostly	8
9	collective actions	9
10	A first quantitative synthesis of the information found in the Press concerning	10
11	actors engaged in conflicts shows that it is less the reaction of the actual users of	11
12	land (professionals, individuals) than the actions of their representatives (elected	12
13	representatives, associations, representatives of the public authorities) that are	13
14	reported in newspapers (Figure 16.9). Among these representatives, municipal	14
15	elected officials and local or generalist associations are those that initiate most of	15
16	the actions covered by the Press, whereas the representatives of State authorities,	16
17	municipal elected officials and professional users are the group of actors who are	17
18	the most contested.	18
19	Among the conflicts triggered by groups opposing the urbanization of	19
20	agricultural land, three scales of conflicts can be distinguished that correspond to	20
21	different categories of contested objects and uses. They are the conflicts related	21
22	to regional development, those related to the management of municipal land, and	22
23	those related to the consequences of urbanization (Cadene, 1990).	23
24	In the first case, the conflictual interactions develop at the level of the sub-	24
25	region, through alliances between elected officials and associations who oppose	25
26	representatives of the public authorities accused of supporting private developers,	26
27	or the managers of regional development and planning (Table 16.2). In the	27
28	case of conflicts related to the management of municipal land, the conflictual	28
29	interactions only involve members of the municipality. The municipal council	29
30	plays an important role here. Finally, the conflicts triggered by actors who protest	30
31	against the nuisance and constraints generated by agricultural activities develop	31
32	mostly at the scale of the municipal territories and their neighbouring areas. They	32
33	involve local environmental associations, and municipal officials who oppose the	33
34	professional representatives of the agricultural or agribusiness sector.	34

16.3.3. The influence of the socio-economic context on the emergence of conflicts

As mentioned above, whether a conflict emerges or not depends on the ability of certain actors to perceive environmental changes, and to use information that enables them to evaluate the nature of the constraints caused by the close proximity or juxtaposition of certain incompatible land uses and their associated facilities and to initiate consultation with the actors at the origin of the contested uses. From a geographical perspective, one may ask in what social-spatial contexts all three criteria are met.

We have highlighted that there are statistically significant correlations² between the social-economic profile of municipalities³ and the probability that a conflict is located within these municipalities. We have based our calculations, not on the location of the objects/facilities that are causing the conflicts, but on the location of the local actors (residents, professionals, elected representatives, local associations...) that initiated the conflictual process.

The test of influence of this geographic factor on the number of conflicts per municipality (Table 16.3) and the number of conflicts per resident (Table 16.4) reveals that the municipalities with a "rural centre" profile are those that are the most prone to conflict, if we compare the number of conflicts to the number of municipalities with this profile. These municipalities are the most populated of the peri-urban zone with a rural morphology (5,000 inhab./town), their population growth is reduced and they are characterised by population ageing. They are often principal county towns. This indicator of conflictuality therefore seems strongly related to the population density, which increases the number of actors liable to engage in conflict.

² The spatial correlations are assessed using a Chi-squared test based on contingency tables of the number of conflicts and of the total municipal population, per class of factors.

³ This typology was developed by the Agreste department of agricultural statistics, based on census data collected by the INSEE between 1990 and 1999.

Table 16.3 Influence of the social-economic profile of the municipality on the number of conflicts per municipality (the conflictual intensity corresponds here to the relation between the number of municipalities affected by one or several of the inventoried conflicts and the total number of municipalities with the profile)

	Origin of the actors who initiated the conflict			Preventive conflicts		Remedial conflicts	
	Number of municipalities with the profile	Number of municipalities identified	Conflictual intensity of the municipalities with the profile	Number of municipalities identified	Conflictual intensity of the municipalities with the profile	Number of municipalities identified	Conflictual intensity of the municipalities with the profile
<ul style="list-style-type: none"> • <u>Geographical sectors</u> • <i>Paris metropolis</i> 	-	28	-				
<ul style="list-style-type: none"> • <i>Urbanized Peri-urban (Outside typology)</i> • <u>Type of socio-economic profile</u> 	-	15	-				
• Upper-class resid.	202	22	0.11	17	0.08	5	0.02
• Middle-class resid.	292	27	0.09	19	0.06	8	0.03
• Traditional rural	247	13	0.05	9	0.04	4	0.016
• Rural villages	92	9	0.10	5	0.05	4	0.04°
• Rural centres	187	36	0.19**	27	0.14**	9	0.05°
• Total	1020	107	0.15	77	0.07	30	0.03

** $P < 0,01$; ° $P > 0,1$

When we compare the number of conflicts with the total number of inhabitants in the municipalities with the same socio-economic profile, we find that the residents of municipalities with the 'upper-class resid.' and 'middle-class resid.' profiles are those that present the highest rate of conflictuality.

The municipalities with the 'upper-class resid.' profile are characterized by slow population growth (between 1990 and 1999), a high percentage of retired people and professional people with managerial or executive positions and a high rate of individual houses. It must be noted that agricultural spaces in these municipalities are smaller in terms of area and that forested zones are larger. These municipalities tend to be located on the Eastern side of the region, mainly in the Yvelines *département* but also in the Val d'Oise and Essonne.

The municipalities with the 'middle-class resid.' profile are characterized by a slightly faster population growth (between 1990 and 1999) and a larger percentage of young households. The municipalities with middle class populations in 1999 and whose conflictual rate per inhabitant is the highest are those that are situated on the fringes of the Yvelines and Essonne *départements* (symbolic conflicts related to the implementation of wind turbines) and in the new town of Sénart (conflicts related to the construction of public utility infrastructures, a prison, a camping site for itinerant people, etc). They are the municipalities in which large housing construction programmes were implemented in the 1990s and whose residential function is relatively diffuse.

Thus, even though their numbers are smaller, the 'local' actors (residents, farmers, elected representatives, local associations) of the residential rural zones are proportionally more reactive than those of denser zones. This correlation applies in the case of preventive conflicts, whereas, in that of remedial conflicts, the populations of municipalities with a 'middle-class resid.' and a 'rural village' profiles are those that have the highest rate of conflictuality.

Table 16.4 Influence of the social-economic profile of the municipality on the number of conflicts per municipality (the conflictual intensity of the profile corresponds here to the relation between the number of municipalities affected by one or several of the inventoried conflicts and the total number of residents of the municipalities with that profile)

	Origin of the actors who initiated the conflict			Preventive conflicts		Remedial conflicts

** $P < 0,01$; * $P < 0,05$

16.4. Conclusion: Conflicts and Regulation of the Use of Agri-urban Resources as Reported by the Press

The information provided by the Press indicates that the uses of agri-urban resources are regulated through social processes, and more particularly through protests against the development of regulations or infrastructures serving urban and non-agricultural activities. A number of these conflicts are related to the implementation of urban waste management facilities and to certain unplanned temporary uses of open spaces (caravan sites, outdoor recreation uses, etc.). Indeed, the urban consumption of agricultural land is regulated, and the degradation of the water and atmospheric resources circulating between the different peri-urban territories is controlled by means of protest against these uses.

Other articles from the Press in our collection reveal, however, that other types of conflicts also play a part in this regulation; these conflicts involve protests against the impact of certain agricultural facilities or practices on the resources destined for urban consumption. The nature of the groups of actors initiating these processes of regulation is determined, on the one hand, by their ability to show the links between the resources under threat and the contested facilities or practices, and, on the other, their ability to approach hierarchical or influence networks so as to be able to take action at the appropriate governance level (i.e. territorial, governmental or economic authorities).

We have also shown that all these conditions were met, in the case of preventive conflicts, within upper- and middle-class residential rural municipalities, and, in the case of remedial conflicts, within middle-class residential rural municipalities, as well as in the newly attractive rural villages. We can deduce from this that though the spatial morphology of municipalities explains the nature of the protected resources and of the contested objects, it is the 'residential rural' profile of the actors that conditions their ability to engage in a conflict that is reported by the Press. Our results confirm the general intuition of Ley and Mercer (1980).
